## Preface

A constraint can intuitively be thought of as a restriction on a space of possibilities. Every piece of knowledge can be interpreted as narrowing the scope of this space, hence, as a constraint. It is not surprising, therefore, that constraints arise naturally in most areas of human endeavor. They are the most general means for formulating regularities that govern the computational, physical, biological and social worlds. For instance, the three angles of a triangle sum to 180 degrees; the four bases that make up DNA strands can only combine in particular orders; the sum of the currents flowing into a node must equal zero; Susan and John cannot both teach at the same time. Such restrictions represent useful pieces of knowledge from diverse disciplines, yet they share one feature in common: they identify the impossible, narrow down the realm of possibilities and, thus, permit us to focus more effectively on the possible.

Constraint problems have proven successful in modeling mundane cognitive tasks such as vision, language comprehension, default reasoning, diagnosis, scheduling, temporal and spatial reasoning. They allow for a natural, declarative formulation of what has to be satisfied, without the need to say how it has to be satisfied.

The current book provides a comprehensive in-depth coverage of the theory that underlies constraint processing algorithms as they emerged in the past three decades, primarily in the area of Artificial Intelligence.

This book aims at readers in diverse areas of computer science including Artificial Intelligence, Databases, Programming Languages, Systems, as well as fields related to computer science such as operation research, management science and applied mathematics.

The book focuses on the fundamental tools and principles that underlie reasoning with constraints, with special emphasis on the representation and analysis of algorithms. The book takes the reader in a step by step manner through definitions, examples, theory, algorithms and complexity analysis. It is intended primarily to graduate students, senior undergraduates, researchers and practitioners and could be used in a quarter/semester course dedicated to this topic, or as a reference book in a general class on artificial intelligence or optimization techniques. To accommodate different levels of reading, some chapters can be omitted without disturbing the flow of readings. Every chapter starts from the basic and practical aspects of its topic, and proceeds to the more advanced aspects, including those under current research.

The book focuses on constraints over discrete and finite domains. It describes the basic principles underlying relational representation first, and presents processing algorithms divided into two main categories: Inference-based and search-based. Search algorithms are characterized by backtracking search and its various enhancements, while inference algorithms are presented through a variety of constraint propagation methods (also known as consistency enforcing methods). Hybrid algorithms are also presented. A Graph-

based view of both types of algorithms is emphasized throughout the book, to enhance the understanding and analysis of the various methods.

# Chapter 1

## Introduction

The notion of a constraint is one with which we are all very familiar in our day-to-day lives. We are used to dealing with situations in which, for example, the memory in our computers is constrained to hold a finite number of bytes, or only a limited number of hours remain until an important deadline arrives. Such problems, though we may not like them, rarely give us reason to pause. The situation becomes more complicated, however, as the number of constraints that must be satisfied simultaneously and the number of variables involved begin to grow. We find that it can take excruciatingly long to decide on the seating arrangement of guests for a formal dinner party or to get a large group of friends to agree on a movie for a night out.

In an even more complicated example, we can imagine the difficulty in scheduling classrooms for a semester of university instruction. We would need to find a classroom for every course while simultaneously satisfying the constraints that no two classes may be held in the same classroom at the same time, no professor can teach in two different classrooms at the same time, no class may be scheduled in the middle of the night, all classes must be offered in appropriately sized rooms or lecture halls, certain classes must not be scheduled at the same time, and so on.

As the complexity of the problem grows, it becomes appropriate to call on the help of computers to find an acceptable solution. In order to do so, computer scientists have devised languages to model constraint satisfaction problems and have developed methods for solving them. Using the language of constraints, computers have modeled mundane cognitive tasks such as vision, language comprehension, default reasoning, and abduction, as well as tasks that require high levels of human expertise such as scheduling, design, diagnosis, and temporal and spatial reasoning. In general, the tasks posed in the language of constraints are computationally intractable (NP-hard).

Over the last two to three decades, a great deal of theoretical and experimental research has been focused on developing general algorithms for solving constraint satisfaction prob-

lems, on identifying restricted subclasses that can be solved efficiently, and on developing approximation algorithms. This book will describe the theory and practice underlying such constraint processing methods.

The rest of the chapter is divided into two parts. First is an informal overview of constraint networks, starting with common examples of problems that can be modeled as constraint satisfaction problems and followed by an overview of the book along its chapters. Second is a review of mathematical concepts relevant to our discussion throughout the book.

## 1.1 Overview

### 1.1.1 Introduction to constraint networks

In general, problems involving constraints include two important components. First of all, every constraint problem must include *variables*, objects or items that can take on a variety of values. The set of possible values for a given variable is called its *domain*. For example, in trying to find an acceptable seating arrangement for a dinner party, we may choose to see the chairs as our variables, each with the same domain, which is the list of all guests.

It is important to note that there is often more than one way to model a problem. We could just as logically have decided that the guests would be the variables and that their domains would be the set of chairs at the table. In this case, with a (hopefully) one-to-one correspondence between chairs and guests, the choice makes little difference, but in other cases, one formulation of a problem may lend itself more readily to solution techniques than another.

The second component to every constraint problem is the set of constraints themselves. *Constraints* impose some kind of limitation on the values that a variable, or a combination of variables, may be assigned. If the host and hostess must sit at the two ends of the table, then their choices of seats are constrained. If two feuding guests must not be placed next to or directly opposite one another, then we must include this constraint as part of the overall problem statement.

Such a model including variables, their domains, and constraints is called a *constraint network*. Other terms used are *constraint problem* or *constraint store*. We use the term “network” to reflect the historical perspective when focus was initially restricted to sets of constraints whose dependencies can naturally be captured by simple graphs as well as to emphasize the importance of the constraint dependency structure for reasoning algorithms.

A *solution* is an assignment of a single value from its domain to each variable such that no constraint is violated. A problem may have one, many, or no solutions. A problem

that has one or more solutions is termed *satisfiable* or *consistent*. If there is no possible assignment of values to the variables that satisfies all the constraints, then the network is termed *unsatisfiable* or *inconsistent*.

Typical tasks over constraint networks are: determining whether a solution exists, finding one or all solutions, finding whether a partial instantiation can be extended to a full solution, and finding an optimal solution relative to a given cost function. Such problems are referred to as *constraint satisfaction problems* or *CSPs* for short.

### 1.1.2 Examples of constraint problems

We next give several common examples of problems that can be modeled as constraint satisfaction problems, including both simple, toy problems that help illustrate the principles involved, as well as more complex, real-world problems. At this point the specification of the constraints will be made rather informally. We revisit some of these examples in more detail in the next chapter and throughout the book.

#### The n-queens problem

A classic example frequently used to demonstrate constraint satisfaction problems is the  $n$ -queens problem. The  $n$ -queens problem asks us to place  $n$  queens on an  $n \times n$  chess board, so that the placement of no queen constitutes an attack on any other. One possible constraint network formulation of the problem is as follows: there is a variable for each column of the chess board  $x_1, \dots, x_n$ , the domains of the variables are the possible row positions  $D_i = \{1, \dots, n\}$ , and the constraint on each pair of columns is that the two queens must not be on the same row or diagonal. One special property of this problem is that the number of variables is always the same as the number of values in each domain.

#### Crossword puzzles

Crossword puzzles have also been used in evaluating algorithms for solving constraint problems. The problem asks us to assign words from the dictionary (or from a given set of words) either vertically or horizontally according to certain constraints. If we allow each word to be placed in any space of the correct length, a possible constraint network formulation of the problem in Figure 1.1 is as follows: there is a variable for each square that can hold a character, the domains of the variables are dictated by the alphabet letters, and the constraints are dictated by the input of possible words:

$\{HOSES, LASER, SHEET, SNAIL, STEER, ALSO, EARN, HIKE, IRON, SAME$   
 $EAT, LET, RUN, SUN, TEN, YES, BE, IT, NO, US\}$

1	2	3	4	5
		6		7
	8	9	10	11
		12	13	

Figure 1.1: A crossword puzzle

So, for example, there is a constraint over the variables  $x_8, x_9, x_{10}, x_{11}$  that allows assigning only the four-letter words from the list to these four variables. The constraint can be described by the relation  $C = \{(A, L, S, O), (E, A, R, N), (H, I, K, E), (I, R, O, N), (S, A, M, E)\}$ . This means that  $x_8, x_9, x_{10}, x_{11}$  can be assigned, respectively, either  $\{A, L, S, O\}$  or  $\{E, A, R, N\}$ , and so on. A solution to the constraint problem will generate an assignment of letters to the squares so that only the legal words are entered.

## Map coloring and k-colorability

The map coloring problem is a well known problem that asks whether it is possible to color a map with only four colors when no two adjacent countries may share the same color. The problem was open for many years, and only recently was it positively solved.

Many resource allocation and communication problems can be abstracted to a more general form of this problem, known in the field of classical graph theory as *k-colorability*. Here, the map is abstracted to a graph with a node for each country and an edge joining any two countries that are neighbors. Given a graph of arbitrary size, the problem is to decide whether or not the graph can be colored with only  $k$  colors such that any two adjacent nodes in the graph must be of different colors. If the answer is yes, then a possible  $k$ -coloring of the graph's nodes should be given.

The graph  $k$ -colorability problem is a constraint satisfaction problem where there is a variable for each node in the graph, the domains of the variables are the possible colors (e.g., for every variable  $x_i$ , its domain is  $D_i = \{red, blue, green\}$  or  $D_i = \{1, 2, 3\}$ ), and the constraints are that every two adjacent nodes must be assigned different values (e.g.,  $A \neq B$ ). A specific example is given in Figure 1.2 where the variables are the countries denoted  $A, B, C, D, E, F, G$ . A solution to this constraint satisfaction problem is a legal  $k$ -coloring of the graph. A property of  $k$ -colorability problems is that their constraints are inequality constraints which appear in many problems and are among the “loosest”

Figure 1.2: A map coloring problem

or “weakest” of constraints. A solution to the graph-coloring problem in Figure 1.2 using three colors is ( $A = \text{red}$ ,  $D = \text{green}$ ,  $E = \text{blue}$ ,  $B = \text{blue}$ ,  $F = \text{red}$ ,  $C = \text{red}$ ,  $G = \text{green}$ ).

## Configuration and design

Configuration and location problems are a particularly interesting class for which constraint satisfaction formalism can be used. These problems arise in applications as diverse as automobile transmission design, micro-computer system configuration, and floor-plan layout. We consider here a simple example from the domain of architectural site location. Consider the map in Figure 1.3 <sup>1</sup>, showing eight lots available for development. Five developments are to be located on these lots: a recreation area, an apartment complex, a cluster of 50 single-family houses, a large cemetery, and a dumpsite. Assume the following information and conditions are given:

- The recreation area should be near the lake.
- Steep slopes are to be avoided for all but the recreation area.
- Poor soil should be avoided for those developments that involve construction, namely the apartments and the family houses.
- The highway, being noisy, should not be near the apartments, the housing, or the recreation area.
- The dumpsite should not be visible from the apartments, the houses, or the lake.
- Lots 3 and 4 have bad soil.

---

<sup>1</sup>This example is due to Nadel.

- Lots 3, 4, 7, and 8 are on steep slopes .
- Lots 2, 3, and 4 are near the lake.
- Lots 1 and 2 are near the highway.

Figure 1.3: Development map

The problem of siting the five developments on the eight available lots so as to satisfy the given conditions can be naturally formulated as a constraint satisfaction problem. A variable is associated with each development:

- *Recreation, Apartments, Houses, Cemetery, and Dump*

The eight a priori possible sites for the developments constitute the common domain for the variables:

- $Domain = \{1, 2, 3, 4, 5, 6, 7, 8\}$

The information and conditions above are the basis for the constraints on the variables.

## Huffman-Clowes scene labeling

One of the earliest constraint satisfaction problems was introduced in the early 1970's. This problem concerns the three-dimensional interpretation of a two-dimensional drawing. Huffman and Clowes [156] developed a basic labeling scheme of the arcs in block world picture graph, where + stands for convex edge, − for a concave edge, and → for occluding boundaries. They demonstrated that the possible combination of legal labelings associated with different junctions in such scenes can be enumerated as in Figure 1.4. The interpretation problem is to label the junction of a given drawing such that every

junction is labeled according to one of its legal labelings and such that edges common to two junctions will receive the same label. The possible consistent labelings of a cube are presented in Figure 1.5. One formulation of this problem assigns variables for the lines in the figure with the domains being the possible labelings  $\{+, -, \rightarrow, \leftarrow\}$ . The constraints will restrict the labeling of adjacent lines in a junction according to the junction type.

Figure 1.4: Huffman-Clowes junction labelings

## Scheduling problems

One of the most practical application for constraint problems is scheduling. Such tasks involve scheduling activities or jobs, such that certain resource and temporal precedence constraints are satisfied. Well known problem classes are job-shop scheduling (where a typical resource is the availability of a machine for processing certain tasks) and timetabling problems, requiring to schedule classrooms and teachers to classes and to time slots such that natural constraints are satisfied. In such problems it is common to associate the tasks with variables and their domain with the starting time of the task, and the constraints restricts those domains based on the problems constraints. A simple demonstrating example will be given in Chapter 2.

So far we gave examples of problems and their informal description as constraint problems. A formal treatment will be given in Chapter 2. This chapter concludes with overview of the book chapters and with mathematical background of concepts used throughout the book.

## 1.2 Book chapters overview

The book provides a comprehensive description of methods for processing and solving constraint problems. Techniques for processing constraints can be classified into two main categories: (1) search and (2) inference, and these techniques may also be combined. As

Figure 1.5: Solutions: (a) stuck on left wall, (b) stuck on right wall, (c) suspended in mid-air, (d) resting on floor.

mentioned, solving constraint problem is hard. The technical term used is NP-complete (see mathematical foundations).

Both search and inference offer methods that are systematic and complete, as well as other methods that are stochastic and incomplete. Complete algorithms are guaranteed to solve the problem if a solution exists or to decide that the problem is inconsistent. Incomplete algorithms, or approximation sometimes solve hard problems quickly, however they are not guaranteed to solve the problem even if given unbounded amount of time and space.

**Inference.** Chapters 3 and 4 as well as Chapters 8 and 9 focus on inference algorithms. Inference algorithms reason through the creation of desirable equivalent problems through problem reformulation. Most often, they create simpler problems that are easier to solve by a subsequent search algorithm. Occasionally, inference methods can even deliver a solution or prove the inconsistency of the network without the need for any further search.

In Chapter 3 we focus on the main concepts associated with inference methods for constraint networks which are called *local consistency* algorithms. Such algorithms take a telescopic view of subparts of the constraint network and demand that they contain no obviously extraneous or contradictory parts. For example, if a network consists of several variables  $x_1, \dots, x_n$ , all with domains  $D = \{1, \dots, 10\}$ , and if  $x_1$  is constrained such that its value must be strictly greater than the value of every other variable, then it is easy to infer that there is no need for the value 1 in  $x_1$ 's domain. Even if we ignore the whole network for the time being and focus only on  $x_1$  and  $x_2$ , for example, we can see that if  $x_1$  is instantiated with the value of 1, then there is no possible assignment of value to  $x_2$  that satisfies the constraint. In the language of constraint networks, the value 1 is *inconsistent* and should be removed from  $x_1$ 's domain because there is no solution to the problem that assigns  $x_1 = 1$ . (We could similarly reason that the value 10 should be removed from

the domain of  $x_2$ .)

In general *local consistency* algorithms (also known as or constraint propagation) are polynomial algorithms that transform a given constraint network into an equivalent, yet more explicit, network by deducing new constraints which are added to the problem. For example, the most basic consistency algorithm which we will present, called *arc-consistency*, ensures that any legal value in the domain of a single variable has a legal match in the domain of any other selected variable. This is the level of consistency-enforcing that we saw in our example. *Path-consistency* ensures that any consistent solution to any two variables is extensible to any third variable, and, in general, *i-consistency* algorithms guarantee that any locally consistent instantiation of  $i - 1$  variables is extensible to any  $i^{th}$  variable. One can transform a given network to an *i-consistent* one by inferring some constraints. However, we will show that enforcing *i-consistency* is computationally expensive; it can be accomplished in time and space exponential in  $i$ . Moreover, these methods are not guarantee to find a solution. Sometimes however, they eliminate domain values to the point of completely emptying one or more domains, in which case they are able to declare the network *inconsistent*. All these methods and concepts will be elaborated in Chapter 3.

Chapter 4 as well as Chapter 8 continue to focus on more advanced inference methods, some of which can provide a complete solution to the problem by making the problem *globally consistent*. We will define such concepts and present less expensive directional consistency algorithms that enforce *global consistency* only relative to a certain variable ordering such as Adaptive-consistency, will be presented. This is an inference algorithm that is typical of a class of variable-elimination algorithm. A unifying description of such algorithms is the focus of Chapter 8. Chapters 3 and 4 expose the readers to structure-based analysis and parameters, such as *induced-width* that will accompany many of the subsequent chapters.

**Search.** The focus of Chapters 5 and 6 is on complete search algorithms. The most common algorithm for performing systematic search is *backtracking*, which traverses the space of partial solutions in a depth-first manner. Each step in the search represents the assignment of a value to one additional variable, thus extending the current partial (candidate) solution. When a variable is encountered such that none of its possible values are consistent with the current partial solution (a situation referred to as a *dead-end*), backtracking takes place. Namely, the algorithm returns to an earlier variable and attempts to assign it a new value such that the dead-end can now be avoided. The best performance of backtracking algorithm occurs when the algorithm is able to successfully assign a value to every variable without encountering any dead-ends. In such a case, backtracking is both time and space linear in the number of variables. Worst-case performance, however, while still requiring only linear space, is exponential in time.

Improvements to backtracking have focused on the two phases of the algorithm: mov-

ing forward (look-ahead schemes) described in Chapter 5, and backtracking (look-back schemes), the focus of Chapter 6. When moving forward to extend a partial solution, look-ahead schemes perform some computation to decide which variable (and even which of that variable's values) to choose next in order to enhance the efficiency of the search. Variables that participate in many constraints maximally constrain the rest of the search space and are thus preferred. In choosing a value from the domain of the selected variable, however, the least constraining value is preferred, in order to maximize options for future instantiations.

Look-back schemes are described in Chapter 6. They are invoked when the algorithm encounters a dead-end and they perform two functions: One, they decide how far to backtrack by analyzing the reasons for the dead-end, a process often referred to as *back-jumping*. Two, they record the reasons for the dead-end in the form of new constraints, so that the same conflict will not arise again, a process known as *constraint learning* or *no-good recording*.

Chapter 7 describes approximation algorithms for search, in particular, a class known as *Stochastic local search* strategies (SLS). Those have been recently reintroduced into the satisfiability and constraint satisfaction literature under the umbrella name *GSAT* (*Greedy SATisfiability*). These methods move in a hill-climbing manner in the space of complete instantiations of all the variables. The algorithm improves its current instantiation by iteratively changing (or ‘flipping’) the value of the variable to maximize the number of constraints satisfied. Such search algorithms are incomplete, may get stuck in a local maxima of their guiding cost function, and cannot always prove inconsistency. Nevertheless, when equipped with some heuristics for randomizing the search or for revising the guiding criterion function (constraint reweighting), they were shown successful in solving large and hard problems that are frequently difficult for backtracking-style search.

Chapter 9 takes the reader again to an inference algorithm. It concentrates on a structure-based compilation method called *tree-clustering*. It belongs to *structure-driven algorithms* that take advantage of the fact that it is possible to depict constraint networks as graphs where nodes represent variables and edges represent constraints. These techniques emerged from an attempt to topologically characterize constraint problems that are tractable. The basic network structure that support tractability is a tree. This has been observed repeatedly in constraint networks, complexity theory and database theory. Most other graph-based techniques can be viewed as transforming a given network into a meta-tree. For example, *tree-clustering* compiles a constraint problem into an equivalent tree of subproblems whose respective solutions can be efficiently combined into a complete solution. Algorithm is quite related to tree-clustering, and both are time and space exponentially bounded in a parameter of the constraint graph called induced-width.

Chapter 7 center on SAT. It specialize all the methods studied in general for CSPs to the special case of SAT. These include the main search algorithm known as DP-

backtracking, the specialized variable-elimination algorithm Directional resolution as well as specialized local search methods.

Chapter 10 focus on hybrid of search and inference methods. When a problem is computationally hard for directional consistency algorithms, it can be solved by bounding the amount of consistency-enforcing (e.g. arc- or path-consistency) and augmenting the algorithm with a search component. As described, bounded inference can be done as preprocessing to search or during search. The chapter presents, the *cycle-cutset scheme* combining search and inference, which is exponentially bounded by the constraint graph's *cycle-cutset*. It then extends this approach to a general parameterized hybrid scheme whose parameter  $b$  bounds the level of inference allowed. Such combined methods allow also tradeoff between time and space.

Chapter 11 extends the theory of tractable constraint problem by looking at special constraints. The chapter will present a general theory for identifying the tractability of constraint problems based on the constraint themselves using algebraic closure properties. These includes implicational and max-ordered constraints. Additional tractable classes exploit notions such as tight domains and tight constraints row-convex constraints, as well as causal networks.

In Chapter 12, special classes of constraints associated with temporal reasoning, that has received much attention in the last decade, will be introduced. These tractable classes include subsets of what is known as the *qualitative interval algebra* expressing relationships such as time interval  $A$  overlaps or precedes time interval  $B$ , as well as quantitative binary linear inequalities over the Real numbers of the form  $X - Y \leq a$ .

Chapter 13 extends the main task of constraint processing to general combinatorial optimization. It is often the case that the problem at hand induces preferences among solutions. Such problems can be expressed by augmenting the constraint problem with a cost function. The chapter extends both search, inference, complete and incomplete approaches to optimization. It summarizes the two most well known approaches for combinatorial optimization developed in Operation Research: Branch and Bound and dynamic programming. The chapter introduces these algorithms from the constraint framework perspective and contrast methods such as integer programming with their constraint methods counterparts.

An important aspect to constraint networks, that of modeling a given problem within this framework, is addressed to a limited extent only, in this book via sporadic examples and excises. One reason is that this aspect is somewhat an art and is not formally well understood. Chapter 14, the final chapter, provides a window towards a language approach for addressing the modeling issue. It provides an introduction a class of languages that exploit constraint processing algorithms known as Constraint logic programming.

### 1.2.1 Reading through the book

Some chapters of this book are more advanced and technically demanding than others. We will denote by an asterisk those sections and chapters that can be skipped without disturbing the flow of the book.

## 1.3 Mathematical background

The formalization of constraint networks relies upon concepts drawn from the related areas of discrete mathematics, logic, the theory of relational databases, and graph theory. This section is a compilation of the mathematical knowledge needed for understanding the formalization of constraint networks and the analyses presented in subsequent chapters. Here we present the basic notations and definitions for sets, relations, operations on relations, and graphs. For those readers already familiar with these topics, a skim of this material will suffice to ensure your understanding of notation used in this book.

### 1.3.1 Sets, domains, and tuples

A set is a collection of distinguishable objects, and an object in the collection is called a *member* or an *element* of the set. A set cannot contain the same object more than once, and its elements are not ordered. If an object  $x$  is a member of set  $A$ , we write  $x \in A$ ; if an object  $x$  is not a member of set  $A$ , we write  $x \notin A$ . A set can be defined explicitly by listing the members of the set or implicitly by stating a property satisfied by elements of the set. For example,  $A = \{1, 2, 3\}$  and  $A = \{x \mid x \text{ an integer and } 1 \leq x \leq 3\}$  both represent the same set with three members, 1, 2, and 3. If each element of a set  $A$  is also an element of set  $B$ , then we write  $A \subseteq B$  and say that  $A$  is *subset* of  $B$ . Set  $A$  is a *proper subset* of  $B$ , written  $A \subset B$ , if  $A \subseteq B$  but  $A \neq B$ .

Given two sets  $A$  and  $B$ , we can also define new sets by applying set operations: the *intersection* of two sets  $A$  and  $B$  is the set  $A \cap B = \{x \mid x \in A \text{ and } x \in B\}$ , the *union* of two sets  $A$  and  $B$  is the set  $A \cup B = \{x \mid x \in A \text{ or } x \in B\}$ , and the *difference* of two sets  $A$  and  $B$  is the set  $A - B = \{x \mid x \in A \text{ and } x \notin B\}$ . A set containing no members is called an *empty set* and is denoted  $\emptyset$ . The number of elements in a set  $S$  is called the *size* (or *cardinality*) of the set and is denoted  $|S|$ . Two sets  $A$  and  $B$  are *disjoint* if they have no elements in common; that is, if  $A \cap B = \emptyset$ .

The *domain* of a variable is simply a set that lists all of the possible objects that a variable can denote or all of the possible values that a variable can be assigned. A *k-tuple* (or simply a *tuple*) is a sequence of  $k$  not necessarily distinct objects denoted by  $(a_1, \dots, a_k)$ , and an object in the sequence is called a *component*. The *Cartesian product*

(or simply the *product*) of a list of domains  $D_1, \dots, D_k$ , written  $D_1 \times \dots \times D_k$ , is the set of all  $k$ -tuples  $(a_1, \dots, a_k)$  such that  $a_1$  is in  $D_1$ ,  $a_2$  is in  $D_2$ , and so on.

**Example 1.3.1** Let  $D_1 = \{\text{black, green}\}$  and  $D_2 = \{\text{apple juice, coffee, tea}\}$ . The Cartesian product  $D_1 \times D_2$  is the set of tuples  $\{(\text{black, apple juice}), (\text{black, coffee}), (\text{black, tea}), (\text{green, apple juice}), (\text{green, coffee}), (\text{green, tea})\}$ .  $\square$

### 1.3.2 Relations

Given a set of variables  $X = \{x_1, \dots, x_k\}$ , each associated with a domain  $D_1, \dots, D_k$  respectively, a *relation*  $R$  on the set of variables is any subset of the Cartesian product of their domains. The set of variables on which a relation is defined is called the *scope* of the relation, denoted  $\text{scope}(R)$ . Each relation that is a subset of some product  $D_1 \times \dots \times D_k$  of  $k$  domains is said to have *arity*  $k$ . If  $k = 1, 2$ , or  $3$ , then the relation is called a *unary*, *binary*, or *ternary* relation, respectively. If  $R = D_1 \times \dots \times D_k$ , then  $R$  is called a *universal* relation. We will frequently denote a relation defined on a scope  $S$  by  $R_S$ .

**Example 1.3.2** Let  $D_1 = \{\text{black, green}\}$  be the domain of variable  $x_1$  and let  $D_2 = \{\text{apple juice, coffee, tea}\}$  be the domain of variable  $x_2$ . The set of tuples  $\{(\text{black, coffee}), (\text{black, tea}), (\text{green, tea})\}$  is a relation on  $\{x_1, x_2\}$ , since the tuples are a subset of the product of  $D_1$  and  $D_2$ . The scope of this relation is  $\{x_1, x_2\}$ .  $\square$

The empty set is another example of a relation. The scope of the empty relation is itself the empty set.

## Representing relations

Relations are sets of tuples defined over the same scope, and, as discussed above for sets, they may be defined either explicitly or implicitly. For example, let  $R$  be a relation on the set of variables  $\{x_1, x_2\}$ , where  $D_1 = \{\text{black, green}\}$  and  $D_2 = \{\text{apple juice, coffee, tea}\}$ . Then the relation  $R_1$  on the scope  $\{x_1, x_2\}$  given by  $R_1 = \{(\text{black, coffee}), (\text{black, tea}), (\text{green, tea})\}$  and  $R_2 = \{(x_1, x_2) \mid x_1 \in D_1, x_2 \in D_2, \text{ and } x_1 \text{ is before } x_2 \text{ in dictionary ordering}\}$  both represent the same relation. Using arithmetic expressions we can also write  $x_1 \leq x_2$  more succinctly, where  $\leq$  is a lexicographic ordering in this case.

Two additional ways to express a relation explicitly make use of tables and (0,1)-matrices. In a table representation, each row is a tuple, and each column corresponds to one component of the tuple. Each column is identified by the variable associated with that component (in the database community, the names of columns are called attributes). The ordering of the columns is inconsequential; two relations that differ only in the ordering of their columns are considered to be the same relation.

In the (0,1)-matrix representation, a binary relation between two variables  $x_i$  and  $x_j$  is represented as a (0,1)-matrix with  $|D_i|$  rows and  $|D_j|$  columns by imposing an ordering on the domains of the variables. A 0-entry at row  $a$  column  $b$  means that the pair consisting of the  $a$ th element of  $D_i$  and the  $b$ th element of  $D_j$  is not permitted; a 1-entry means that the pair is permitted. The (0,1)-matrix representation can be generalized to nonbinary relations by increasing the number of dimensions of the matrix.

Figure 1.6 shows two alternative representations of the binary relation  $R$  on the scope  $\{x_1, x_2\}$ , where  $D_1 = \{\text{black, green}\}$  and  $D_2 = \{\text{apple juice, coffee, tea}\}$ .

		$\underline{x_2}$		
		apple juice		
		coffee		
		tea		
$\underline{x_1}$	$x_2$			
black	coffee			
black	tea			
green	tea			

$\underline{x_1}$		$\begin{bmatrix} 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}$		
black		0	1	1
green		0	0	1

(a) table
(b) (0,1)-matrix

Figure 1.6: Two alternative views of relation  $R = \{(\text{black, coffee}), (\text{black, tea}), (\text{green, tea})\}$ .

We often use special languages to express languages. One such language is applied to Boolean domains, another is Numerical constraints using mathematical algebraic expressions.

## Operations on relations

Having introduced the mathematical notion of a relation, we can now consider operations on relations. First we consider how general set operations apply to relations, and then we discuss three operations specific to relations: selection, projection, and join.

*Intersection, union, and difference.* Given two relations,  $R$  and  $R'$ , on the same scope, the intersection of  $R$  and  $R'$ , denoted  $R \cap R'$ , is the relation containing all tuples that are in both  $R$  and  $R'$ ; the union  $R \cup R'$  is the relation containing all the tuples that are in either  $R$  or  $R'$  or both, and the difference  $R - R'$  is the relation containing those tuples that are in  $R$  but not in  $R'$ . The scope of the resulting relations is the same as the scope of the relations  $R$  and  $R'$ .

**Example 1.3.3** Let the relations  $R$ ,  $R'$ , and  $R''$  be as shown in Figure 1.7. The relations  $R$  and  $R'$  have the same scopes  $\{x_1, x_2, x_3\}$ , so the set operations intersection, union,

Figure 1.7: Three relations.

and difference are well-defined for these sets. Since the scope of  $R''$  is not the same, none of these three operations is well-defined for  $R''$  and either of the other two relations. Figure 1.8 shows the relations  $R \cap R'$ ,  $R \cup R'$ , and  $R - R'$ .  $\square$

a	b	c
c	b	s

(c)  $R - R'$

Figure 1.8: Example of set operations intersection, union, and difference applied to relations.

*Selection.* Let us now consider those operations specific to relations. A selection takes a relation  $R$  and yields a new relation that is the subset of tuples of  $R$  with specified values on specified variables. That is to say, in a table representation of a relation, selection chooses a subset of the rows of a relation. Let  $R$  be a relation, let  $x_1, \dots, x_k$  be variables in the scope of  $R$ , and let  $a_i$  be an element of  $D_i$ , the domain of  $x_i$ . We use the notation  $\sigma_{x_1=a_1, \dots, x_k=a_k}(R)$  to denote the selection of those tuples in  $R$  that have the value  $a_1$  for variable  $x_1$ , the value  $a_2$  for variable  $x_2$ , and so on. An alternative and more succinct notation is of the form: if  $Y = \{x_1, \dots, x_k\}$  and  $t = (a_1, \dots, a_k)$ , then  $\sigma_{Y=t}(R)$  is equivalent to  $\sigma_{x_1=a_1, \dots, x_k=a_k}(R)$ . The scope of the resulting relation is the same as the scope of  $R$ .

*Projection.* Projection takes a relation  $R$  and yields a new relation that consists of the tuples of  $R$  with certain components removed. In the table representation of a relation, projection chooses a subset of the columns of a relation. Let  $R$  be a relation, and let

$Y = \{x_1, \dots, x_k\}$  be a subset of the variables in the scope of  $R$ . We use the notation  $\pi_Y(R)$  to denote the projection of  $R$  onto  $Y$ , that is, the set of tuples obtained by taking in turn each tuple in  $R$  and forming from it a new, smaller tuple, keeping only those components associated with variables in  $Y$ . Projection specifies a subset of the variables of a relation, and the scope of the resulting relation is that subset of variables.

*Join.* The join operator takes two relations  $R_S$  and  $R_T$  and yields a new relation that consists of the tuples of  $R_S$  and  $R_T$  combined on all their common variables in  $S$  and  $T$ . Let  $R_S$  be a relation with scope  $S$  and  $R_T$  be a relation with scope  $T$ . A tuple  $r$  is in the join of  $R_S$  and  $R_T$ , denoted  $R_S \bowtie R_T$ , if it can be constructed according to the following steps: (i) take a tuple  $s$  from  $R_S$ , (ii) select a tuple  $t$  from  $R_T$  such that the components of  $s$  and  $t$  agree on the variables that  $R_S$  and  $R_T$  have in common (that is, on the variables in  $S \cap T$ ), and (iii) form a new tuple  $r$  by combining the components of  $s$  and  $t$ , keeping only one copy of those components corresponding to variables in  $S \cap T$ . The scope of the resulting relation is the union of the scopes of  $R$  and  $S$ , that is,  $S \cup T$ . We can see that a join of two relations with the same scopes is equivalent to the intersection of the two relations.

**Example 1.3.4** Let the relations  $R$ ,  $R'$ , and  $R''$  be as shown in Figure 1.7. Figure 1.9 shows examples of the selection, projection, and join operations applied to these relations. The relation  $\sigma_{x_3=c}(R')$  consists of those tuples in  $R'$  that have the value  $c$  for variable  $x_3$ . The relation  $\pi_{\{x_2, x_3\}}(R')$  consists of the tuples in  $R'$ , each with the component that corresponds to the variable  $x_1$  removed; only the components that correspond to variables  $x_2$  and  $x_3$  are kept. Duplicate entries are removed, since a relation is a set and sets do not contain duplicate objects. The relation  $R' \bowtie R''$  consists of tuples that are combinations of pairs of tuples from  $R'$  and  $R''$  which agree on their common variables  $\{x_2, x_3\}$ . To construct  $R' \bowtie R''$ , we consider each tuple in  $R'$ , match it up with all possible tuples in  $R''$  that agree with it on the common variables, and delete duplicate components associated with these variables. For example, the tuple  $(b, b, c)$  in  $R'$  agrees with the tuples  $(b, c, 2)$  and  $(b, c, 3)$  in  $R''$ , resulting in the tuples  $(b, b, c, 2)$  and  $(b, b, c, 3)$ . Similarly, the tuple  $(c, b, c)$  in  $R'$  results in the tuples  $(c, b, c, 2)$  and  $(c, b, c, 3)$ . The tuple  $(c, n, n)$  in  $R'$  does not agree with any tuple in  $R''$  on variables  $x_2$  and  $x_3$ , so no additional tuples are added to  $R' \bowtie R''$ .  $\square$

### 1.3.3 Graphs: general concepts

**Definition:** A *graph*  $G = (V, E)$  is a structure which consists of a finite set of *vertices*, or *nodes*,  $V = \{v_1, \dots, v_n\}$  and a set of *edges*, or *arcs*,  $E = \{e_1, e_2, \dots, e_l\}$ . Each edge  $e$  is incident to an unordered pair of vertices  $\{u, v\}$  which are not necessarily distinct (as in

$x_1$	$x_2$	$x_3$		$x_2$	$x_3$		$x_1$	$x_2$	$x_3$	$x_4$

c	b	c		n	n		b	b	c	3
							c	b	c	2
							c	b	c	3

(a)  $\sigma_{x_3=c}(R')$       (b)  $\pi_{\{x_2, x_3\}}(R')$       (c)  $R' \bowtie R''$

Figure 1.9: Example of selection, projection, and join operations on relations.

Figure 1.10: Two graphs: (a) undirected and (b) directed.

the case of a loop). Although the vertices are unordered, they will often be written as an ordered pair  $(u, v)$ . If  $e = (u, v) \in E$  we say that  $e$  connects  $u$  and  $v$  and that  $u$  and  $v$  are *adjacent* or *neighbors*. The degree  $d(u)$  of a vertex  $u$  in a graph is the number of its adjacent vertices.

A *path* is a sequence of edges  $e_1, e_2, \dots, e_k$  such that  $e_i$  and  $e_{i+1}$  share an endpoint. Namely, if  $e_i = (u_1, v_1)$  and  $e_{i+1} = (u_2, v_2)$ , then  $v_1$  and  $u_2$  are the same. It is also convenient to describe a path using its vertices  $v_0, v_1, \dots, v_k$ , where  $e_i = (v_{i-1}, v_i)$ . Node  $v_0$  is called the start-vertex of the path,  $v_k$  is called the end vertex, and the length of the path is  $k$ . A *cycle* is a path whose start and end vertices are the same. A path is called *simple* if no vertex appears on it more than once. A cycle is called *simple* if no vertex other than the start-end vertex appears more than once and the start-end vertex does not appear elsewhere in the cycle. If for every two vertices  $u$  and  $v$  in the graph there exists a path from  $u$  to  $v$ , then the graph is said to be *connected*. An undirected graph with no cycles is called a *tree*. Given a subset of the nodes  $S$  in the graph  $G$ , a *subgraph* relative to  $S$ , denoted  $G_S$  is the graph whose nodes are in  $S$  and whose edges are all edges in  $G$  that are incident only to nodes in  $S$ . A graph is *complete* if every two nodes are adjacent.

A *clique* in a graph is a complete subgraph.

A *directed graph* (*digraph*) is defined similarly to an undirected graph except that the pair of endpoints of an edge is now ordered; the first endpoint is called the *start-vertex* of the edge, and the second is called the *end-vertex*. The edge  $e = (u, v)$ , also denoted  $u \rightarrow v$ , is said to be directed from  $u$  to  $v$ . The *outdegree* of a vertex  $v$  is the number of edges which have  $v$  as their start-vertex; *in-degree* of  $v$  is the number of edges which have  $v$  as their end-vertex. The set of nodes that point to node  $u$  is called its *parents* and is denoted  $pa(u)$ . Similarly, the set of vertices to which  $u$  points is called the set of *child nodes* of  $u$  and is denoted  $ch(u)$ . A *directed path* is a sequence of edges  $e_1, e_2, \dots, e_k$  such that the end-vertex of  $e_{i-1}$  is the start-vertex of  $e_i$ . A directed path is a *directed cycle* if the start-vertex of the path is the same as the end-vertex. A directed graph is *strongly connected* if for every vertex  $u$  and every vertex  $v$  there is a directed path from  $u$  to  $v$ . A directed graph is *acyclic* if it has no directed cycles. The following example demonstrates the above definitions.

**Example 1.3.5** The graph  $G_1$  in Figure 1.10a is an undirected graph over vertices  $\{A, B, C, D, E, F\}$ . The edge  $e = (A, B)$  is in the graph while  $(B, C)$  is not. The sequence  $(A, B, D, F)$  is a path whose start-vertex is  $A$  and whose end-vertex is  $F$ . The path  $(A, B, D, C, A)$  is a simple cycle. The degree of vertex  $D$  is 3. The subgraph  $\{A, B, E\}$  is a clique. The subgraph  $\{A, B, E, D\}$  contains four edges:  $\{(A, B), (B, E), (A, E), (B, D)\}$ . The graph  $G_2$  in Figure 1.10b is a directed graph which is acyclic. The indegree of  $D$  is 2, and its outdegree is 1. In other words,  $D$  in  $G_2$  has two parents and one child node.  $\square$

### 1.3.4 Background in complexity

[to be written]

## 1.4 Chapter notes

Section 1.2 already provides a brief overview of the constraint area. The area of constraint started with the work of Waltz [156] in vision for identifying 3-dimensional interpretation from 2-dimensional drawings. It was followed by the seminal work of Montanari introducing the concept of Constraint networks [112] formally, establishing many of the concepts that became the building blocks of this area such as path-consistency. Mackworth [100] further extended and popularized this work defining the notion of local node, arc and path consistency and discuss the implication of such methods on search. There are several surveys on aspects of constraint-based reasoning including Mackworth [101], Dechter [36], Kumar [89]. There is also an alternative full-length book treatment of the subject by

Tsang [143] and a new book on constraint programming [105]. For surveys on constraint programming see [72]. More recent surveys can be found in [39].

For mathematical foundation see Cormen, Leiserson, and Rivest [25] is a useful reference for some of the elements of discrete mathematics discussed in this chapter and for material on asymptotic notation and analyzing algorithms, which is used but not presented in this book. There is a close relationship between constraint networks and the relational data model in database systems, as both use relations as the primary notation for representing data or knowledge. Maier [104] and Ullman [144] are useful references for relational databases and the mathematical language for expressing queries to the database called the relational algebra, from which our operations on relations are drawn.

A parallel significant development is *Constraint programming*. These are programming languages that address modeling issues focusing on various languages for expressing constraints. Such languages allowed the practical solution of many constraint satisfaction algorithms [105].

## 1.5 Exercises

1. Let  $R_{xy} = \{(a, b), (c, d), (d, e)\}$  and  $R_{yz} = \{(b, c), (e, a), (b, d)\}$ . Compute:

- (a)  $R_1 \cup R_2$ ,
- (b)  $R_1 - R_2$ ,
- (c)  $R_{xy} \bowtie R_{yz}$ ,
- (d)  $\pi_x R_{xy}$
- (e)  $\sigma_{x=c}(R_{xy} \times R_{yz})$ ,

# Chapter 2

## Constraint Networks

In this chapter we will begin the process of formally modeling constraint satisfaction problems as constraint networks. The initial formal work on constraint networks introduced in the paper by Montanari [112] was restricted to binary constraints, defined on pairs of variables only. Also, some of the beginning work and especially experiments was limited to the binary case. Indeed it is possible to show that any set of constraints can be mapped to the binary case. Nevertheless the book will always assume the general case when constraints are defined on arbitrary size sets of variables and will refer to the special case of binary constraints explicitly, when appropriate.

### 2.1 Constraint networks and constraint satisfaction

#### 2.1.1 The basics of the framework

A *constraint network*  $\mathcal{R}$  consists of a finite set of *variables*  $X = \{x_1, \dots, x_n\}$ , with respective *domains*  $D = \{D_1, \dots, D_n\}$  which list the possible values for each variable  $D_i = \{v_1, \dots, v_k\}$ , and a set of *constraints*  $C = \{C_1, \dots, C_t\}$ . Thus a constraint network can be viewed as a triple  $(X, D, C)$ .

A constraint  $C_i$  is a relation  $R_i$  defined on a subset of variables  $S_i$ ,  $S_i \subseteq X$ , which denotes their simultaneous legal value assignments.  $S_i$  is called the *scope* of  $R_i$ . If  $S_i = \{x_{i_1}, \dots, x_{i_r}\}$ , then  $R_i$  is a subset of the Cartesian product  $D_{i_1} \times \dots \times D_{i_r}$ . Thus a constraint can also be viewed as a pair  $C_i = \langle S_i, R_i \rangle$ . When the scopes identity is clear, we will often identify the constraint  $C_i$  with its relation  $R_i$ . Otherwise, for clarity a constraint relation may be denoted  $R_{S_i}$ . A scope will be denoted explicitly as  $\{x, y, z\}$ , or, when no confusion can arise, as  $xyz$ . For example, we can denote by  $R_{xyz}$ , (or by  $\langle xyz, R \rangle$ ) the constraint defined over the variables  $x, y$ , and  $z$  whose relation is  $R$ . The set of scopes  $S = \{S_1, \dots, S_i, \dots, S_t\}$  is called the *scheme* of the network. Without loss of generality,

we assume that only a single constraint is defined over a subset  $S_i$  in  $S$ , namely if  $i \neq j$ , then  $S_i \neq S_j$ .

The *arity* of a constraint refers to the cardinality, or size, of its scope. A *unary constraint* is defined on a single variable. A *binary constraint* is defined on two variables. A *binary constraint network* is one that has only unary and binary constraints.

## Formulating the n-queen problem

Consider a possible constraint network formulation of the  $n$ -queens problem. The columns of the chess board will be the variables,  $x_1, \dots, x_n$ , and the domains of the variables are the possible row positions,  $D_i = \{1, \dots, n\}$ . Assigning a value  $j \in D_i$  to a variable  $x_i$  corresponds to placing a queen in row  $j$  on column  $x_i$  of the chess-board. The constraints are binary and state that no two queens should attack one another, namely that no two queens should be placed on the same row or diagonal. Figure 2.1(a) shows the chess-board for the 4-queens problem, and Figure 2.1(b) shows all of the constraints in relational form. For example, the tuple  $(1,3)$  is in the relation  $R_{12}$  defined over  $\{x_1, x_2\}$ , which means that simultaneously assigning the value 1 to variable  $x_1$  and the value 3 to variable  $x_2$  is allowed by the constraint. The complete definition of the 4-queen  $\mathcal{R} = (X, D, C)$ , where  $X = \{x_1, x_2, x_3, x_4\}$ , and for every  $i$   $D_i = \{1, 2, 3, 4\}$ . There are 6 constraints,  $C_1 = R_{12}$ ,  $C_2 = R_{13}$ ,  $C_3 = R_{14}$ ,  $C_4 = R_{23}$ ,  $C_5 = R_{24}$  and  $C_6 = R_{34}$ .

### 2.1.2 Solution of a constraint network

**Instantiation.** When a variable is assigned a value from its domain, we say that the variable has been *instantiated*. An *instantiation* of a subset of variables is an assignment from its domain to each variable in the subset. Formally an instantiation of a set of

variables  $\{x_{i_1}, \dots, x_{i_k}\}$  is a tuple of ordered pairs  $(\langle x_{i_1}, a_{i_1} \rangle, \dots, \langle x_{i_k}, a_{i_k} \rangle)$ , where each pair  $\langle x, a \rangle$  represents an assignment of the value  $a$  to the variable  $x$ , where  $a$  is in the domain of  $x$ . We also use the notation  $(x_1 = a_1, \dots, x_i = a_i)$ . For simplicity, however we often abbreviate  $(\langle x_1, a_1 \rangle, \dots, \langle x_i, a_i \rangle)$  to  $\bar{a} = (a_1, \dots, a_i)$ , and perceive an instantiation or a tuple as a relation over some scope having a single tuple.

**Satisfying a constraint.** An instantiation or a tuple  $\bar{a}$ , satisfies a constraint  $R$  iff the components of the tuple  $\bar{a}$  associated with  $R$ 's scope are in the relation  $R$ . For example, let  $R_{xyz} = \{(1, 1, 1), (1, 0, 1), (0, 0, 0)\}$ . then the instantiation  $\bar{a}$  whose scope is  $\{x, y, z, t\}$  given by  $\bar{a} = (x = 1, y = 1, x = 1, t = 0)$ , satisfies  $R_{xyz}$  because its projection on  $\{x, y, z\}$  is  $(1, 1, 1)$  which is an element of  $R$ . However, the instantiation  $(x = 1, y = 0, x = 0, t = 0)$ , violates  $R$ .

**Solution.** A *solution* of a constraint network  $\mathcal{R} = (X, D, C)$  where  $X = \{x_1, \dots, x_n\}$ , is an instantiation of all its variables such that all the constraints are satisfied. A projection of a tuple  $\bar{a}$  on a subset of its scope  $S$  is denoted also by  $\bar{a}[S_i]$  (as well as  $\pi_{S_i}(\bar{a})$ ). The solution relation  $sol(\mathcal{R})$ , also denoted  $\rho_X$ , is defined by:

$$sol(\mathcal{R}) = \{\bar{a} = (a_1, \dots, a_n) | a_i \in D_i, \forall S_i \in \text{scheme of } \mathcal{R}, \bar{a}[S_i] \in R_i\}.$$

A network of constraints is said to *express* or *represent* the relation of all its solutions.

**A consistent partial instantiation.** A partial instantiation is consistent if it satisfies all of the constraints that have no uninstantiated variables. More formally, let  $S$  be a subset of variables, and let  $\bar{a}$  be an instantiation over  $S$ .  $\bar{a}$  is *consistent* relative to network  $\mathcal{R}$  if and only if for all  $S_i$  in the scheme of  $\mathcal{R}$ , s.t.,  $S_i \subseteq S$ ,  $\bar{a}[S_i] \in R_{S_i}$ . If we have a constraint network  $\mathcal{R}$  over  $X$  and a subset of variables  $A \subseteq X$ ,  $sol(A)$  or  $\rho_A$  is the set of all consistent instantiations over  $A$ .

Consider again the constraint network for the 4-queens problem. There is a constraint between every pair of variables, hence the scheme of the network is given by  $\{\{x_1, x_2\}, \{x_1, x_3\}, \dots, \{x_3, x_4\}\}$ . Consider the set of variables  $Y = \{x_1, x_2, x_3\}$ . The instantiation  $\bar{a} = (\langle x_1, 1 \rangle, \langle x_2, 4 \rangle, \langle x_3, 2 \rangle)$  shown in Figure 2.2(a) is consistent, since

$$\begin{aligned} \bar{a}[\{x_1, x_2\}] &= (1, 4) & \text{and} & & (1, 4) &\in R_{12} \\ \bar{a}[\{x_1, x_3\}] &= (1, 2) & \text{and} & & (1, 2) &\in R_{13} \\ \bar{a}[\{x_2, x_3\}] &= (4, 2) & \text{and} & & (4, 2) &\in R_{23} \end{aligned}$$

although  $\bar{a}$  is not part of any full solution. There are only two full solutions to the 4-queens problem, as shown in Figure 2.2(b) and (c). The 4-queen problem represents the relation  $\rho_{1234} = \{(2, 4, 1, 3)(3, 1, 4, 2)\}$ .

Figure 2.2: Not all consistent instantiations are part of a solution: (a) A consistent instantiation that is not part of a solution. (b) The placement of the queens corresponding to the solution (2, 4, 1, 3). (c) The placement of the queens corresponding to the solution (3, 1, 4, 2).

Figure 2.3: A crossword puzzle

## The crossword puzzle

We return now to our crossword puzzle example from Chapter 1. (See again Figure 2.3.) A formal constraint network formulation is as follows: there is a variable for each square that can hold a character,  $x_1, \dots, x_{13}$ , the domains of the variables are the alphabet letters, and the constraints are the possible words. For this example, the constraints are given by:

$$R_{1,2,3,4,5} = \{(H,O,S,E,S), (L,A,S,E,R), (S,H,E,E,T), (S,N,A,I,L), (S,T,E,E,R)\}$$

$$R_{3,6,9,12} = \{(A,L,S,O), (E,A,R,N), (H,I,K,E), (I,R,O,N), (S,A,M,E)\}$$

$$R_{5,7,11} = \{(E,A,T), (L,E,T), (R,U,N), (S,U,N), (T,E,N), (Y,E,S)\}$$

$$R_{8,9,10,11} = R_{3,6,9,12}$$

$$R_{10,13} = \{(B,E), (I,T), (N,O), (U,S)\}$$

$$R_{12,13} = R_{10,13}.$$

The reader should verify that the consistent partial assignments over the set of variables  $\{x_1, x_2, x_3, x_4, x_5, x_6, x_9, x_{12}\}$  are:

$$\begin{aligned} \rho_{1,2,3,4,5,6,9,12} = & \{(H, O, S, E, S, A, M, E), (L, A, S, E, R, A, M, E), \\ & (S, H, E, E, T, A, R, N), (S, N, A, I, L, L, S, O), (S, T, E, E, R, A, R, N)\}. \end{aligned}$$

An alternative constraint formulation of the crossword puzzle associates each first digit that can start a word as a variable and its possible word assignments as values. In this case, the variables are  $x_1$  (1, horizontal),  $x_2$  (3, vertical),  $x_3$  (5, vertical),  $x_4$  (8, horizontal),  $x_5$  (12, horizontal), and  $x_6$  (10, vertical). The scheme of this problem is

$$\{\{x_1, x_2\}, \{x_1, x_3\}, \{x_4, x_2\}, \{x_4, x_3\}, \{x_5, x_2\}, \{x_6, x_4\}, \{x_6, x_5\}\}$$

because there is a constraint between  $x_1$  (1, horizontal) and  $x_2$  (3, vertical), and so on. The domains are:  $D_1 = \{hoses, laser, sheet, snail, steer\}$ ,  $D_2 = D_4 = \{also, earn, hike, iron, same\}$ ,  $D_3 = \{eat, let, run, sun, ten, yes\}$  and  $D_5 = D_6 = \{be, it, no, us\}$ . The constraint between  $x_1$  and  $x_2$ , is given by

$$R_{12} = \{(hoses, same)(laser, same), (sheet, earn)(snail, also), (steer, earn)\}.$$

A partial consistent tuple in this case is :  $(x_1 = sheet, x_2 = earn, x_3 = ten, x_4 = iron, x_5 = no)$ . Note that this formulation of the problem is binary, namely, involving constraints on pairs of variables only. Also note that the network has no solutions.

### 2.1.3 Constraint graphs

A constraint network can be represented by a graph called a (primal) *constraint graph*. Each node represents a variable, and the arcs connect all nodes whose variables are included in a constraint scope of the problem's scheme. The lack of an arc between two nodes indicates that the direct constraint, the one specified in the input, between the two is the *universal relation* allowing every tuple. Figure 2.4(a) shows the constraint graph associated with our second formulation of the crossword puzzle, and Figure 2.4(b) shows the constraint graph of the 4-queens problem, which is complete.

## A scheduling example

The constraint framework is useful for expressing and solving scheduling problems. Consider the problem of scheduling five tasks, T1, T2, T3, T4, T5, each of which takes one hour to complete. The tasks may start at 1:00, 2:00, or 3:00. Any number of tasks can

Figure 2.4: Constraint graphs of (a) the crossword puzzle and (b) the 4-queens problem.

be executed simultaneously, subject to the restrictions that T1 must start after T3, T3 must start before T4 and after T5, T2 cannot execute at the same time as T1 or T4, and T4 cannot start at 2:00.

With five tasks and three time slots, we can model the scheduling problem by creating five variables, one for each task, and giving each variable the domain  $\{1:00, 2:00, 3:00\}$ . Another possible approach is to create three variables, one for each starting time, and to give each of these variables a domain which is the powerset of  $\{T1, T2, T3, T4, T5\}$ . This requires a tricky means of expressing the constraints and is left as an exercise at the end of the chapter. Adopting the first approach, the problem's constraint graph is shown in Figure 2.5. The constraint relations are shown on the right of the figure.

The (primal) constraint graph is well defined for both binary and non-binary constraints. However, a hypergraph representation maintains the association between arcs and constraints in the non-binary case more accurately.

**Definition 2.1.1 (hypergraphs)** A hypergraph is a structure  $\mathcal{H} = (V, S)$  that consists of vertices  $V = \{v_1, \dots, v_n\}$  and a set of subsets of these vertices  $S = \{S_1, \dots, S_l\}$ ,  $S_i \subseteq V$ , called hyperedges. The hyperedges differ from regular edges in that they "connect" (or are defined over) more than two variables.

In the *constraint hypergraph* representation of a constraint problem, nodes represent the variables, and *hyperarcs* (drawn as regions) are the scopes of constraints. Namley, they group those variables that belong to the same scope. A related representation is the *dual constraint graph*. A *dual constraint graph* represents each *constraint scope* by a node and associates a labeled arc with any two nodes whose *constraint scopes* share variables. The arcs are labeled by the shared variables. Figure 2.6 depicts the *primal* and the *dual* graphs of our first formulation of the crossword puzzle. Notice that the dual

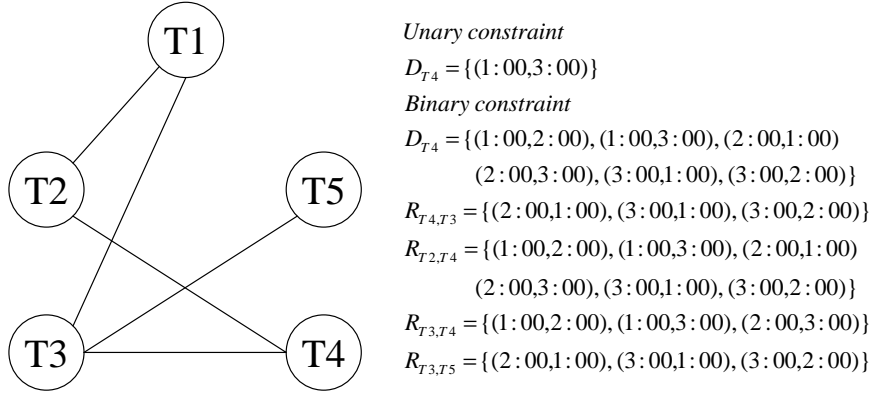

Figure 2.5: The constraint graph and constraint relations of the scheduling problem in Example 1.

graph of the first formulation (Figure 2.6b) is identical to the primal constraint graph of the second formulation (Figure 2.4a). Indeed, the *dual* constraint graph is essentially a

Figure 2.6: Constraint graphs of the crossword problem: (a) primal and (b) dual.

transformation of a nonbinary network into a special type of *binary* network called the *dual problem*, where the constraints are the variables, denoted *c-variables*. The domain of each c-variable ranges over all possible value combinations permitted by the corresponding constraint, and any two adjacent c-variables must obey the restriction that their shared (original) variables must have the same values (i.e., the c-variables are bound by equality constraints). Viewed in this way, any network can be transformed into a binary network and solved by binary network techniques. For the crossword puzzle, both the dual and the primal representations are natural, that is, people frequently will come up with each

of these formulations as their first representation of the problem.

## The Huffman-Claws labeling

Another natural dual-primal formulation can be demonstrated through the Huffman-Clows junction labellings. In one formulation of the problem as a constraint network, variables denote the various junctions in the problem instance, their domains are the possible label combinations on junction types, and the constraints are expressed using  $(0,1)$ -matrices as in Figure 2.8. For example,  $x_i$  denotes junction  $i$  in the cube. Since 1 is a Fork junction, the values of  $x_1$  are the label combinations that can be assigned to such a junction. The constraints require that if an edge connects two junctions, it will get the same label from each junction. The  $(0,1)$ -matrix representation of the constraints assumes that the domains of each junction variable (in Figure 2.7) are ordered from left to right. In this formulation, all the constraints are binary and the constraint graph is identical to the input problem graph. The set of solutions for this problem is depicted in Figure 2.9.

This formulation can also be perceived as the dual graph of a nonbinary formulation whereby the variables are the edges, having the domains of  $\{+, -, \rightarrow, \leftarrow\}$ , and the constraints are binary or ternary depending on the junction types. In the primal constraint graph, two nodes (representing edges) will be connected if they participate in the same junction (see exercises). %endexample

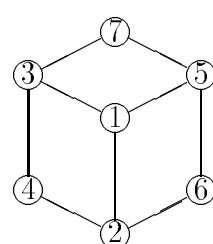

Figure 2.7: Huffman-Clows junction labelings

## 2.2 Numeric and Boolean constraints

Relations provide the underlying meaning of a constraint and a very explicit specification syntax of the allowed tuples, as seen in Figure 2.1b. However, this method of specification can sometimes prove very tedious and unwieldy. In many instances, we can utilize

$$R_{21} = \begin{bmatrix} 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \end{bmatrix} \quad R_{31} = \begin{bmatrix} 0 & 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \end{bmatrix} \quad R_{51} = \begin{bmatrix} 0 & 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \end{bmatrix}$$

$$R_{24} = R_{37} = R_{56} = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 & 0 \end{bmatrix}$$

$$R_{26} = R_{34} = R_{57} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 \end{bmatrix}$$

Figure 2.8: Scene labeling constraint network

Figure 2.9: Solutions: (a) stuck on left wall, (b) stuck on right wall, (c) suspended in mid-air, (d) resting on floor.

mathematical conventions to create a description of the relationships between objects that is more concise or more convenient than the relational description. Two examples of alternative languages for describing constraints are arithmetic constraints and boolean constraints. The first allows more concise expression while the second, in addition to being restricted to bi-valued domains, expresses explicitly the forbidden tuples rather than the legal ones.

### 2.2.1 Numeric Constraints

Numeric, or arithmetic, constraints use the language of arithmetic to express the constraints in a network. Consider expressing our 4-queens problem with numeric constraints.

Instead of describing the constraints by enumerating the allowed elements of each relation, we can very succinctly state that every two variables  $x_i$  and  $x_j$  should satisfy:  $\forall i, j, \quad x_i \neq x_j, \text{ and } |x_i - x_j| \neq |i - j|$  defining the relation

$$R_{ij} = \{(x_i, x_j) \mid x_i \in D_i, x_j \in D_j, x_i \neq x_j, \text{ and } |x_i - x_j| \neq |i - j|\}.$$

In another example, let the domains of the variables be finite subsets of the integers, and let a binary constraint between two variables be a conjunction of linear inequalities of the form  $ax_i - bx_j = c$ ,  $ax_i - bx_j < c$ , or  $ax_i - bx_j \leq c$ , where  $a$ ,  $b$ , and  $c$  are integer constants. For example, the conjunction

$$(3x_i + 2x_j \leq 3) \wedge (-4x_i + 5x_j < 1)$$

is a legitimate constraint between variables  $x_i$  and  $x_j$ . A network with constraints of this form can be formulated as "an integer linear program" where each constraint is defined over two variables, and the domains of the variables are restricted to being finite subsets of the integers.

Linear constraints are a special subclass of numeric constraints widely applicable in the areas of scheduling and temporal and spatial reasoning. Many techniques for treating these type of constraints were developed in the Operations Research (OR) community.

### Cryptarithmic puzzles

One class of toy problems that can be easily formulated with linear constraints are the *cryptarithmic puzzles*, such as: SEND + MORE = MONEY. Here we are asked to replace each letter by a different digit so that the above equation is correct. The constraint formulation of these puzzles will associate each letter with a variable whose domains are the digits  $\{0..9\}$ . The exact formulation of this problem is left as an exercise at the end of the chapter.

### 2.2.2 Boolean constraints and propositional cnf

When the variables of a constraint problem range over two values, we frequently use a boolean propositional language to describe the various relationships. Assume that you would like to invite your friends Alex, Beki, and Chris to a party. Let  $A$ ,  $B$ , and  $C$  denote the propositions "Alex comes", "Beki comes" and "Chris comes", respectively. You know that if Alex comes to the party, Beki will come as well, and if Chris comes, then Alex will too. This can be expressed in propositional calculus as  $(A \rightarrow B) \wedge (C \rightarrow A)$ , or equivalently as  $(\neg A \vee B) \wedge (\neg C \vee A)$ , where the disjunctive formulas  $(\neg A \vee B)$  and  $(\neg C \vee A)$  are called *clauses*. Assume now that Chris came to the party; should you expect to see

Beki? Or, in propositional logic, does the propositional theory  $\varphi - C \wedge (A \rightarrow B) \wedge (C \rightarrow A)$  entails  $B$ ? A common way to answer this query is to assume that Beki will not come and check whether this is a plausible situation (i.e., decide if  $\varphi' = \varphi \wedge \neg B$  is satisfiable). If  $\varphi'$  is unsatisfiable, we can conclude that  $\varphi$  entails  $B$ . Formally, the propositional satisfiability problem (SAT) is to decide whether a given *cnf* theory has a *model*, i.e., an assignment to its proposition that does not violate any clause.

Propositional satisfiability can be described as a CSP, where propositions correspond to the variables, domains are  $\{0, 1\}$ , and constraints are represented by clauses (for example, clause  $(\neg A \vee B)$  allows all the tuples  $(A, B)$  except  $(A = 1, B = 0)$ ).

Propositional variables take only two values  $\{true, false\}$  or “1” and “0.” We denote propositional *variables* by uppercase letters  $P, Q, R, \dots$ , propositional literals (i.e.,  $P, \neg P$ ) stand for  $P = \text{“true”}$  or  $P = \text{“false,”}$  and disjunctions of literals, or *clauses*, are denoted by  $\alpha, \beta, \dots$ . A *unit clause* is a clause of size 1. The notation  $(\alpha \vee T)$ , when  $\alpha = (P \vee Q \vee R)$  is shorthand for the disjunction  $(P \vee Q \vee R \vee T)$ .  $\alpha \vee \beta$  denotes the clause whose literal appears in either  $\alpha$  or  $\beta$ . A formula  $\varphi$  in conjunctive normal form (*cnf*), referred to as a *theory*, is a set of clauses  $\varphi = \{\alpha_1, \dots, \alpha_t\}$  that denotes their conjunction. The set of *models* or *solutions* of a formula  $\varphi$  is the set of all truth assignments to all its variables that do not violate any clause.

In general, a *cnf* theory is a constraint network whose variables are the propositions, the domains have two values  $\{true, false\}$  or  $\{0, 1\}$ . Each clause is a constraint on the corresponding propositional variables. For instance, the *cnf* theory  $\varphi = (A \vee B) \wedge (C \vee \neg B)$  has three variables and two constraints. The constraint  $A \vee B$  expresses the relation  $R_{AB} = \{(01), (10), (11)\}$ .

The structure of a propositional theory can be described by an *interaction graph*. The interaction graph of a propositional theory  $\varphi$ , denoted  $G(\varphi)$ , is an undirected graph that contains a node for each propositional variable and an edge for each pair of nodes that correspond to variables appearing in the same clause. For example, the interaction graph of theory  $\varphi_1 = \{(\neg C), (A \vee B \vee C), (\neg A \vee B \vee E), (\neg B \vee C \vee D)\}$  is shown in Figure 10.6a.

### 2.2.3 Combinatorial circuits diagnosis

Boolean propositional languages are often used to express combinatorial circuits built out of AND, OR, and XOR gates (see Figure ??). The diagnosis task over such circuits can be formulated as a constraint satisfaction problem. In *circuit diagnosis* we are given a description of the circuit composed of inputs combined through the boolean gates to their output. If the expected output and the observed output are different, the task is to identify a subset of the gates that, if assumed to be faulty, can explain the observed output.

Figure 2.10: The interaction graph of theory  $\varphi_1 = \{(\neg C), (A \vee B \vee C), (\neg A \vee B \vee E), (\neg B \vee C \vee D)\}$

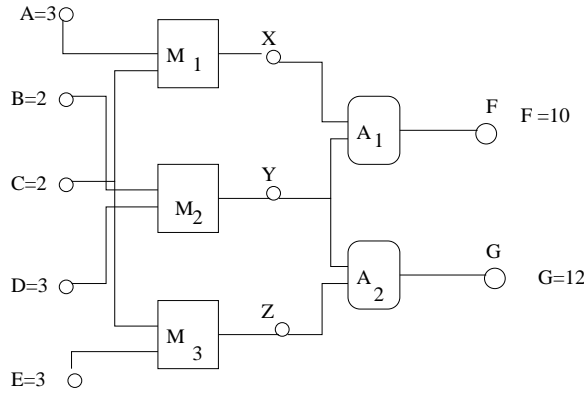

Figure 2.11: A combinational circuit: M is a multiplier, A is an adder

One method of formulating the diagnosis task within a constraint network is to associate each gate, as well as its inputs and outputs, with a variable and then to describe by boolean constraints the relationship between the input and output of each gate under the assumption that the gate is either proper or faulty. Once a fault is observed at the output, the task of explaining the circuit behavior is completed by identifying a set of gates that is assumed faulty. (often the minimal such set is required). Such an explanation amounts to finding type of consistent solution for the formulated network.

In the specific example of Figure 2.11 there are three multipliers and two adders. The constraint formulation will have a variable for each input  $\{A, B, C, D, E\}$ , output  $\{F, G\}$  and intermediate output  $\{X, Y, Z\}$  and for each component  $M_1, M_2, M_3, A_1, A_2$ . The domains of the input and output variables are any number (integer or Boolean if we so choose to restrict the problem). The domain of the components are  $\{0, 1\}$ , when 1 indicate a faulty behavior of the component and 0 a correct behavior. A constraint will be associated with each component variable, its input variables and output variables,

yielding 5 constraints, each defined over 4 variables.

If the input and outputs are Boolean variables, the constraints can be expressed by a Boolean expression. For example, if  $M_1$  is an *AND* gate its associated constraint is:  $M_1 \rightarrow (A \wedge C \rightarrow X)$ . A detailed description of the constraints is requested in the exercises.

## 2.3 Properties of binary constraint networks

Many of the concepts for constraint processing were initially introduced for binary networks. We find it helpful to discuss binary networks separately in this section since many important concepts of constraint processing are easier to digest in this restricted case. In particular, concepts such as minimal network and decomposability, allow deep understanding of issues that underly the general theory of constraints.

### 2.3.1 Equivalence and deduction with constraints

One central concept with which we should be comfortable is constraint deduction or *constraint inference*. New constraints can be inferred from an initial set of constraints. These newly inferred constraints might take the form of constraints between variables that were not initially constrained or might be tightenings of existing constraints. For instance, from the algebraic constraints  $x \geq y$  and  $y \geq z$  we can infer that  $x \geq z$ . In particular, it means that adding the inferred constraint  $x \geq z$  yields an equivalent constraint network. The next example demonstrate such notions using relational representation.

**Example 2.3.1** Consider the graph-coloring problem in Figure 2.12a. The problem

Figure 2.12: (a) A graph  $\mathcal{R}$  to be colored by two colors, (b) an equivalent representation  $\mathcal{R}'$  having a newly inferred constraint between  $x_1$  and  $x_3$ .

can be described by a constraint network with three variables,  $x_1, x_2, x_3$ , one for each

node, all defined on the same domain values  $\{red, blue\}$ , and the inequality constraints:  $R_{21} = R_{32} = \{(blue, red), (red, blue)\}$ . The lack of an arc between  $x_1$  and  $x_3$  represents the universal relation  $R_{13} = \{(red, blue), (blue, red), (red, red), (blue, blue)\}$ . The problem has two solutions:  $\rho_{123} = \{(red, blue, red)(blue, red, blue)\}$ . Assume now that we tighten the constraint between  $x_1$  and  $x_3$ , disallowing the pair  $(\langle x_1, red \rangle, \langle x_3, blue \rangle)$ . Since this pair does not participate in any of the original problem's solutions, this restriction does not alter the set of solutions. In fact, if we add the constraint  $R'_{13} = \{(red, red)(blue, blue)\}$ , we get a new constraint network  $\mathcal{R}'$  having the same set of solutions (see Figure 2.12b). Indeed, the constraint  $R'_{13}$  which enforces  $x_1 = x_3$  can be *inferred* from the original network  $\mathcal{R}$ . The two networks  $\mathcal{R}$  and  $\mathcal{R}'$  are said to be *equivalent*.  $\square$

An inferred constraint can also be viewed as *redundant* relative to a constraint network since its deletion from the network will not change the set of all solutions. For instance, in  $\mathcal{R}'$  the inequality constraint between  $x_1$  and  $x_2$  is redundant since its deletion does not change the set of solutions. The same redundancy exists for each of the other two constraints. However, once  $R'_{12}$  is removed from  $\mathcal{R}'$ , the other constraints are no longer redundant. In summary, two constraint networks are *equivalent* if they are defined on the same set of variables and they express the same set of solutions. A constraint  $R_{ij}$  is redundant relative to  $\mathcal{R}$  iff  $\mathcal{R}$  is equivalent to  $\mathcal{R} - R_{ij}$ .

One type of constraint deduction is accomplished by the *composition* operation.

**Definition 2.3.2 (composition)** *Given two binary or unary constraints  $R_{xy}$  and  $R_{yz}$ , the composition  $R_{xy} \cdot R_{yz}$  generates the binary relation  $R_{xz}$  defined by:*

$$R_{xz} = \{(a, b) | a \in D_x, b \in D_z, \exists c \in D_y \text{ s.t. } (a, c) \in R_{xy} \text{ and } (c, b) \in R_{yz}\}$$

An alternative, operational definition is formulated in terms of the join and projection operators:

$$R_{xz} = R_{xy} \cdot R_{yz} = \pi_{\{x,z\}}(R_{xy} \bowtie R_{yz}).$$

In the example in Figure 2.12a we deduce that  $R'_{13} = \pi_{\{x_1, x_3\}}(R_{12} \bowtie R_{23}) = \{(red, red), (blue, blue)\}$ , thus yielding the equivalent network in Figure 2.12b. The composition operation can be described via boolean matrix multiplication when binary relations are expressed using  $(0, 1)$  matrices.

**Example 2.3.3** Continuing with our simple graph-coloring example, the two inequality constraints can be expressed as  $2 \times 2$  matrices having zeros along the main diagonal.

$$R_{12} = \left( \begin{array}{c|cc} & red & blue \\ \hline red & 0 & 1 \\ blue & 1 & 0 \end{array} \right) \quad R_{23} = \left( \begin{array}{c|cc} & red & blue \\ \hline red & 0 & 1 \\ blue & 1 & 0 \end{array} \right)$$

Multiplying two such matrices yields the following two-dimensional identity matrix:

$$R_{12} \cdot R_{23} = R_{13} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \times \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \left( \begin{array}{c|cc} & red & blue \\ \hline red & 1 & 0 \\ blue & 0 & 1 \end{array} \right)$$

It is important to note that composition, in general, is not distributive with respect to intersection, namely:  $R_{12} \cdot (R_{23} \cap R'_{23}) \neq (R_{12} \cdot R_{23}) \cap (R_{12} \cdot R'_{23})$ , as you will be required to demonstrate in the exercises.  $\square$

**Example 2.3.4** For example....  $\square$

### 2.3.2 The minimal and the projection networks

In his seminal paper [112], Montanari considers the expressive power of binary networks. The question is whether an arbitrary relation can be a set of solutions to some underlying binary constraint network having the same set of variables.

In fact, most relations cannot be represented by a collection of binary constraints, since there are many more different relations on  $n$  variables than there are networks of binary constraints on  $n$  variables. Given  $n$  variables each having a domain of size  $k$ , cardinality arguments dictate that the number of different relations on  $n$  variables is  $2^{k^n}$ , which is far greater than the number of different binary constraint networks,  $2^{k^2 n^2}$ . The proof of this argument is left as an exercise at the end of the chapter. In those special cases where a relation is expressible by a binary constraint network, such a representation is highly desirable, since it may require less space to specify.

A relation that cannot be expressed by a binary network may still be approximated by one. Let's consider the approximation of a relation by its binary *projection network*.

**Definition 2.3.5 (projection network)** *The projection network of a relation  $\rho$  is obtained by projecting  $\rho$  onto each pair of its variables. Formally, if  $\rho$  is a relation over  $x_1, \dots, x_n$ , its projection network,  $P(\rho)$  is defined by the network  $\mathcal{P} = \{P_{ij}\}$ ,*

$$P_{ij} = \{(a_i, a_j) \mid \exists t \in \rho \text{ s.t. } t[x_i] = a_i, t[x_j] = a_j\}$$

**Example 2.3.6** Let  $\rho_{123} = \{(1, 1, 2)(1, 2, 2)(1, 2, 1)\}$ . The projection network  $P(\rho)$  includes the constraints  $P_{12} = \{(1, 1)(1, 2)\}$ ,  $P_{13} = \{(1, 2)(1, 1)\}$ , and  $P_{23} = \{(1, 2)(2, 2)(2, 1)\}$ . Generating all solutions of  $P(\rho)$  yields  $\text{sol}(P(\rho)) = \{(1, 1, 2)(1, 2, 2)(1, 2, 1)\}$ .  $\square$

What is the relationship between the original relation  $\rho$  and  $P(\rho)$ ? In Example 2.3.6 generating all solutions of  $P(\rho)$  yields back the relation  $\rho$ . But this cannot be characteristic of the general case, else we would have proven that every relation has a binary

network representation by its projection network, and we know this to be false due to the cardinality argument presented earlier. What does hold in general is that the projection network is the best *upper bound network approximation* of a relation. Namely, for every relation  $\rho$ , the solution set of  $P(\rho)$  contains  $\rho$ . Moreover, as we will show, any other upper bound network will express a solution set that includes the projection network's solutions. The following example elaborates.

**Example 2.3.7** Consider a slightly different relation  $\rho$ :

$x_1$	$x_2$	$x_3$
1	1	2
1	2	2
2	1	3
2	2	2

The projection network  $P(\rho)$  has the following constraints:  $P_{12} = \{(1,1)(1,2)(2,1)(2,2)\}$ ,  $P_{23} = \{(1,2)(2,2)(1,3)\}$  and  $P_{13} = \{(1,2)(2,3)(2,2)\}$ . The set of solutions to  $P(\rho)$ ,  $\text{sol}(P(\rho))$ , are:

$x_1$	$x_2$	$x_3$
1	1	2
1	2	2
2	1	2
2	1	3
2	2	2

□

We see that all the tuples of  $\rho$  appear in the solution set of  $P(\rho)$ , while some additional solutions to  $P(\rho)$  are not in  $\rho$ . In general:

**Theorem 2.3.8** *For every relation  $\rho$ ,  $\rho \subseteq \text{sol}(P(\rho))$ .*

**Proof:** Let  $t \in \rho$ . We have to show only that  $t \in \text{sol}(P(\rho))$ , namely that it satisfies every binary constraint in  $P(\rho)$ . This is clearly true since by its definition every pair of values of  $t$  was included, by projection in the corresponding constraint of  $P(\rho)$ . □

Is there another binary network of constraints  $\mathcal{R}'$  whose solution set contains  $\rho$  but is smaller than  $P(\rho)$ ? Perhaps we might discover such a network by tightening the constraints of  $P = P(\rho)$ ? Let's try to eliminate the superfluous tuple  $(2,1,2)$  from  $\text{sol}(P)$  in Example 2.3.7 by deleting the pair  $(2,1)$  from the projection constraint  $P_{12}$ . Unfortunately, if we do this, we also exclude the tuple  $(2,1,3)$  which is in  $\rho$ . And, if we try to exclude  $(2,1,2)$  by deleting the pair  $(1,2)$  from  $P_{23}$  we eliminate  $(1,1,2)$  which is also in  $\rho$ . Lastly, if we exclude  $(2,2)$  from  $P_{13}$ , we will eliminate  $(2,2,2)$ . Indeed,  $P(\rho)$  cannot be tightened any further if its solutions are to include all the tuples in  $\rho$ . In fact,

**Theorem 2.3.9** *The projection network  $P(\rho)$  is the tightest upper bound network representation of  $\rho$ ; there is no binary network  $\mathcal{R}'$ , s.t.  $\rho \subseteq \text{sol}(\mathcal{R}') \subset \text{sol}(P(\rho))$ .*

Consequently, if a relation is not expressible by its projection network, it cannot be expressed by any binary network of constraints.

Theorem 9.5.2 shows that the projection network is the most accurate binary network upper bound for a relation. But is it also the tightest explicit description of that relation  $\text{sol}(P(\rho))$ ? This question leads us to the notion of a partial order of tightness among binary constraint networks. As we have seen in Figure 2.12a and b, the networks  $\mathcal{R}$  and  $\mathcal{R}'$  are semantically equivalent since they represent the same set of solutions, yet  $\mathcal{R}'$  is tighter than  $\mathcal{R}$  using a pairwise comparison of their binary relations.

**Definition 2.3.10** *Given two binary networks,  $\mathcal{R}'$  and  $\mathcal{R}$ , on the same set of variables  $x_1, \dots, x_n$ ,  $\mathcal{R}'$  is at least as tight as  $\mathcal{R}$  iff for every  $i$  and  $j$ ,  $R'_{ij} \subseteq R_{ij}$ .*

Obviously, if  $\mathcal{R}'$  is tighter than  $\mathcal{R}$ , then the solution set of  $\mathcal{R}'$  is contained in the solution set of  $\mathcal{R}$ . However, often one network which is tighter than another still expresses the same set of solutions. Moreover, if we take the intersection of two equivalent networks (by intersecting constraints pairwise), we get a new equivalent network that is tighter than either.

**Definition 2.3.11** *The intersection of two networks  $\mathcal{R}$  and  $\mathcal{R}'$ , denoted  $\mathcal{R} \cap \mathcal{R}'$ , is the binary network obtained by pairwise intersection of the corresponding constraints in the two networks.*

Clearly,

**Proposition 2.3.12** *If  $\mathcal{R}$  and  $\mathcal{R}'$  are two equivalent networks, then  $\mathcal{R} \cap \mathcal{R}'$  is equivalent to and is at least as tight as both.*

For a proof see exercises.

**Example 2.3.13** Consider the network in Figure 2.12a and the network in Figure 2.12b without  $R_{23}$ . Intersecting the two networks yield a equivalent network in Figure 2.12b that is tighter than both.  $\square$

There exists, therefore, a partial order of tightness amongst all networks that are equivalent to each other. If we intersect all these equivalent networks, we get one unique network that is equivalent to all the networks and is at least as tight as all networks. This network is called the *minimal network*. The minimal network  $M(\mathcal{R})$  of a binary network  $\mathcal{R}$  is the tightest network that is equivalent to  $\mathcal{R}$ .  $M(\mathcal{R})$  is also denoted  $M(\rho)$  when  $\rho$  is the set of solutions to  $\mathcal{R}$ .

**Definition 2.3.14** Let  $\{\mathcal{R}_1, \dots, \mathcal{R}_l\}$  be the set of all networks equivalent to  $\mathcal{R}_0$  and let  $\rho = \text{sol}(\mathcal{R}_0)$ . Then the minimal network  $M$  of  $\mathcal{R}_0$  is defined by  $M(\mathcal{R}_0) = \cap_{i=1}^l \mathcal{R}_i$ .

Finally, it is possible to show that the minimal network is identical to the projection network of its set of solutions.

**Theorem 2.3.15** For every binary network  $\mathcal{R}$  s.t.  $\rho = \text{sol}(\mathcal{R})$ ,  $M(\rho) = P(\rho)$ .

**Proof:** Left as an exercise

Figure 2.13 shows the constraint graph and the unary and binary minimal constraints of the 4-queens problem. We denote the binary constraints in the minimal network by  $M_{ij}$ . The unary constraints are the reduced domains. (Compare this network to the equivalent one in Figure 2.1.) The minimal network is perfectly explicit for unary and binary constraints. That is to say, if a pair of values is permitted by the minimal network, then it is guaranteed to appear in at least one solution. Indeed, it immediately follows from Theorem 2.3.15 that,

**Proposition 2.3.16** If  $(a, b) \in M_{ij}$  then  $\exists t \in \text{sol}(M)$  s.t.  $t[i] = a$  and  $t[j] = b$ .

Figure 2.13: The 4-queens constraint network. (a) The constraint graph. (b) The minimal binary constraints. (c) The minimal unary constraints (the domains).

We should note here that finding a single solution of a minimal network of constraints is not guaranteed to be easy. In fact, it is known that deciding if  $\rho$  can be representable by its projection network is NP-hard. It is still not clear, however, whether or not generating a single solution of a minimal network is hard. Empirical experience shows that normally generating a single solution using the minimal network is easy. We do speculate that generating a single solution from the minimal network is hard and we leave this as an exercise.

### 2.3.3 Decomposable networks

One reason that the minimal network does not solve the problem of generating a solution is that, while we can always find easily a partial solution of size 2 that is part of a full solution, we cannot guarantee that we can extend a two variable solution to a third variable. In an easy way given an arbitrary minimal network, unless the minimal network is also *decomposable*.

We know by now that a relation has a binary network representation iff it is equivalent to its projection network. We also know that the projection network is its most explicit form. It turns out, however, that a relation may be representable by a binary network while many of its projections are not.

**Example 2.3.17** Consider the relations

$$\rho = \left( \begin{array}{c|cccc} x & y & z & t \\ \hline a & a & a & a \\ a & b & b & b \\ b & b & a & c \end{array} \right) \quad \pi_{xyz}\rho = \left( \begin{array}{c|ccc} x & y & z \\ \hline a & a & a \\ a & b & b \\ b & b & a \end{array} \right)$$

One can easily verify that  $\rho$  is representable by a binary constraint network. However, the projected relation  $\pi_{xyz}\rho$  is not expressible by binary networks because

$$\pi_{xyz}\rho \subset \text{sol}(P(\pi_{xyz}\rho))$$

□

**Definition 2.3.18** A relation is binary-decomposable if it is expressible by a network of binary constraints and iff each of its projected relations is expressible by a binary network of constraints.

It can be shown that if a relation is decomposable, then the projection network expresses the relation and all its projections. In other words, if  $\rho$  is a decomposable relation and  $S$  is a subset of the variables, then  $\rho_S$  is expressible by the subnetwork of  $P(\rho)$  whose variables are restricted to the variables in  $S$  (see exercises).

## 2.4 Summary

The chapter provides a formal presentation of constraint networks, their solutions and their graph representation. It demonstrates these concepts through several examples. Subsequently it focuses on some formal properties of binary constraint networks.

## 2.5 Chapter Notes

Graphical properties of constraint networks were initially investigated through the class of *binary constraint networks*. Montanari [112] was the first to formally define binary constraint networks. Montanari also introduced most of the concepts mentioned in the second part of this chapter, including minimal network, projection network and decomposable network. He also discussed important notions of constraint propagations which are the focus of the next chapter.

## Exercises

1. Nadel [114] proposes a variant of  $n$ -queens called *confused  $n$ -queens*. The problem is to find all ways to place  $n$ -queens on an  $n \times n$  chess board, one queen per column, so that all pairs of queens *do* attack each other. Propose a formulation of the problem as a constraint network. Identify variables, domains and constraints.
2. (Introductory Combinatorics, R. A. Brualdi, 1977.) A Latin Square of order  $n$  is defined to be an  $n \times n$  array made out of  $n$  distinct symbols (usually the integers  $1, 2, \dots, n$ ) with the defining characteristic that each of the  $n$  symbols occurs exactly once in each row of the array and exactly once in each column. For example,

$$\begin{bmatrix} 3 & 2 & 1 \\ 1 & 3 & 2 \\ 2 & 1 & 3 \end{bmatrix}$$

Orthogonal Latin Squares: Let  $\mathbf{A}$  and  $\mathbf{B}$  be Latin squares of order  $n$  and let the entry in the  $i^{th}$  row and the  $j^{th}$  column of  $\mathbf{A}$  and  $\mathbf{B}$  be denoted as  $a_{ij}$  and  $b_{ij}$ , respectively, with  $i, j = 1, 2, \dots, n$ .  $\mathbf{A}$  and  $\mathbf{B}$  are *orthogonal* if the  $n^2$  order pairs  $(a_{ij}, b_{ij})$  are all distinct. For example, the following juxtaposed Latin Squares are orthogonal:

$$\begin{bmatrix} (3,2) & (2,3) & (1,1) \\ (2,1) & (1,2) & (3,3) \\ (1,3) & (3,1) & (2,2) \end{bmatrix}$$

Propose a formulation of the as a constraint network. Identify variables, domains and constraints.

3. Formulate the scheduling problem appearing in Figure 2.5 where the starting time are the variables as a CSP.

4. Formulate the Huffman-Claws labelling problems as a constraint network where each arc in the drawing is a variable. Draw the primal constraint graph and the dual constraint graph.
5. Formulate the following zebra problem as a constraint network. Provide the variables, domains and constraints. Draw the primal constraint graph, the constraint hypergraph and the dual constraint graph.

The zebra problem: There are five houses in a row, each of a different color, inhabited by women of different nationalities. The owner of each house owns a different pet, serves different drinks, and smokes different cigarettes. The following facts are also known:

The Englishwoman lives in the red house  
 The Spaniard owns a dog  
 Coffee is drunk in the green house  
 The Ukrainian drinks tea  
 The green house is immediately to the right of the ivory house  
 The Oldgold smoker owns the snail  
 Kools are being smoked in the yellow house  
 Milk is drunk in the middle house  
 The Norwegian lives in the first house on the left  
 The Chesterfield smoker lives next to the fox owner  
 The yellow house is next to the horse owner  
 The LuckyStrike smoker drinks orange juice  
 The Japanese smokes Parliament  
 The Norwegian lives next to the blue house

The Problem: who drinks water and who owns the zebra?

6. Provide two formulations for each of the Cryptarithmic problem below as a constraint network; provide the variables, domains and constraints. Draw the primal and the dual constraint graphs. Discuss which formulation is superior in your opinion.

$$(a) \quad \begin{array}{rcccc} & & S & E & N & D \\ + & & M & O & R & E \\ \hline M & O & N & E & Y & \end{array}$$

(b) HOCUS + POCUS = PRESTO

(c) GERALD + DONALD = ROBERT

7. Formulate the 3x3 magic square as a constraint problem. Draw its primal and dual graphs.

A magic square of order  $n$  is an  $n \times n$  array of the integers  $1, 2, \dots, n^2$  arranged so that the sum of every row, column, and the two main diagonals is the same. Since

$$\sum_{i=1}^{n^2} i = \frac{1}{2}n^2(n^2 + 1),$$

the sum must be  $\frac{1}{2}n(n^2 + 1)$ . For example,

$$\begin{bmatrix} 1 & 15 & 24 & 8 & 17 \\ 23 & 7 & 16 & 5 & 14 \\ 20 & 4 & 13 & 22 & 6 \\ 12 & 21 & 10 & 19 & 3 \\ 9 & 18 & 2 & 11 & 25 \end{bmatrix}$$

is a magic square of order 5, each row, column, and main diagonal add up to  $\frac{1}{2}5(5^2 + 1) = 65$ .

8. Think about a problem of your choice that can be formulated as a constraint problem. Describe and formulate as in the above questions.
9. Find the minimal network of the crossword puzzle (Figure 2.3) when the problem is formulated as a set of binary constraints.
10. Consider the following relation  $\rho$  on variables  $x, y, z, t$ .

$$\rho(xyzt) = \{(aaaa)(abbb)(bbac)\}$$

- (a) Find the projection network  $P(\rho)$ . Is  $\rho$  representable by a network of binary constraints? Justify your answer.
- (b) Is the projection  $\pi_{xyz}(\rho)$  representable by a network of binary constraints? Is  $\rho$  decomposable?
- (c) A search space is backtrack-free along an order of its variables,  $d$ , if any partial solution along this order can be extended to a full solution. Can you find an ordering such that  $P(\rho)$  is backtrack-free?
- (d) Is there a binary network representation of  $\rho$  that is decomposable?
11. Prove that if  $\mathcal{R}$  and  $\mathcal{R}'$  are two equivalent networks, then  $\mathcal{R} \cap \mathcal{R}'$  is equivalent to and is at least as tight as both.

12. Let  $R_1$  and  $R_2$  be two binary networks on  $n$  variables and the same domains. Prove that If  $\mathcal{R}$  is tighter than  $\mathcal{R}'$  then  $\text{sol}(\mathcal{R}) \subseteq \text{sol}(\mathcal{R}')$ .
13. Prove: for every binary network  $\mathcal{R}$  whose set of solutions is  $\rho$ ,  $M(\rho) = P(\rho)$ .
14. *Decomposability*
  - (a) Is the set of solutions of the 4-queen problem binary decomposable?
  - (b) Prove that if  $\rho$  is a binary decomposable relation and  $S$  is a subset of its variables, then  $\pi_S(\rho)$  is expressible by the subnetwork restricted to variables in  $S$  of the projection network  $P(\rho)$ .
  - (c) Is the minimal network always decomposable? Prove or show a counterexample.
15. Prove that the number of relations over  $n$  variables with domain size  $k$  is  $2^{k^n}$ , while the number of binary constraint networks is  $2^{k^2 n^2}$ .
16. Hypothesis: Prove that the problem of finding a solution from the minimal network is NP-hard (suggested approach: look at graph coloring problems)
