Description

The FAN7602B is a green current-mode PWM controller. It is specially designed for off-line adapter applications; DVDP, VCR, LCD monitor applications; and auxiliary power supplies.

The internal high-voltage start-up switch and the burst-mode operation reduce the power loss in standby mode. As a result, it is possible to supply 0.5W load, limiting the input power under 1W when the input line voltage is 265V_{AC}. On no-load condition, input power is under 0.3W.

The maximum power can be limited constantly, regardless of the line voltage change, using the power limit function.

The switching frequency is internally fixed at 65kHz.

The FAN7602B includes various protections for the system reliability and the internal soft-start prevents the output voltage over-shoot at start-up.

Pin Definitions

Pin #	Name	Description
1	LUVP	Line Under-Voltage Protection Pin. This pin is used to protect the set when the input voltage is lower than the rated input voltage range.
2	Latch/Plimit	Latch Protection and Power Limit Pin. When the pin voltage exceeds 4V, the latch protection works; the latch protection is reset when the V _{CC} voltage is lower than 5V. For the power limit function, the OCP level decreases as the pin voltage increases.
3	CS/FB	Current Sense and Feedback Pin. This pin is used to sense the MOSFET current for the current mode PWM and OCP. The output voltage feedback information and the current sense information are added using an external RC filter.
4	GND	Ground Pin. This pin is used for the ground potential of all the pins. For proper operation, the signal ground and the power ground should be separated.
5	OUT	Gate Drive Output Pin. This pin is an output pin to drive an external MOSFET. The peak sourcing current is 450mA and the peak sinking current is 600mA. For proper operation, the stray inductance in the gate driving path must be minimized.
6	V _{CC}	Supply Voltage Pin. IC operating current and MOSFET driving current are supplied using this pin.
7	NC	No Connection.
8	V _{STR}	Start-up Pin. This pin is used to supply IC operating current during IC start-up. After start-up, the internal JFET is turned off to reduce power loss.

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Applications Information

1. Start-up Circuit and Soft Start Block

The FAN7602B contains a start-up switch to reduce the power loss of the external start-up circuit of the conventional PWM converters. The internal start-up circuit charges the V_{CC} capacitor with 0.9mA current source if the AC line is connected. The start-up switch is turned off 15ms after IC starts up, as shown in Figure 19. The soft-start function starts when the V_{CC} voltage reaches the start threshold voltage of 12V and ends when the internal soft-start voltage reaches 1V. The internal start-up circuit starts charging the V_{CC} capacitor again if the V_{CC} voltage is lowered to the minimum operating voltage, 8V. The UVLO block shuts down the output drive circuit and some blocks to reduce the IC operating current and the internal soft-start voltage drops to zero. If the V_{CC} voltage reaches the start threshold voltage, the IC starts switching again and the soft-start block works as well.

During the soft-start, the pulse-width modulated (PWM) comparator compares the CS/FB pin voltage with the soft-start voltage. The soft-start voltage starts from 0.5V and the soft-start ends when it reaches 1V and the soft-start time is 10ms. The start-up switch is turned off when the soft-start voltage reaches 1.5V.

Figure 19. Start-up Current and V_{CC} Voltage

2. Oscillator Block

The oscillator frequency is set internally. The switching frequency is 65kHz.

3. Current Sense and Feedback Block

The FAN7602B performs the current sensing for the current-mode PWM and the output voltage feedback with only one pin, pin3. To achieve the two functions with one pin, an internal leading edge blanking (LEB) circuit to filter the current-sense noise is not included because the external RC filter is necessary to add the output voltage feedback information and the current-sense information. Figure 20 shows the current-sense and feedback circuits. R_S is the current-sense resistor to sense the switch current. The current-sense information is filtered by an RC filter composed of R_F and C_F . According to the output voltage feedback information, I_{FB} charges or stops

charging C_F to adjust the offset voltage. If I_{FB} is zero, C_F is discharged through R_F and R_S to lower offset voltage.

Figure 21 shows typical voltage waveforms of the CS/FB pin. The current-sense waveform is added to the offset voltage, as shown in Figure 21. The CS/FB pin voltage is compared with PWM+ that is 1V - Plimit offset. If the CS/FB voltage meets PWM+, the output drive is shut off. If the feedback offset voltage is low, the switch on time is increased. If the feedback offset voltage is high, the switch on time is decreased. In this way, the duty cycle is controlled according to the output load condition. In general, the maximum output power increases as the input voltage increases because the current slope during switch on-time increases.

To limit the output power of the converter constantly, a power-limit function is included. Sensing the converter input voltage through the Latch/Plimit pin, the Plimit offset voltage is subtracted from 1V. As shown in Figure 21, the Plimit offset voltage is subtracted from 1V and the switch on-time decreases as the Plimit offset voltage increases. If the converter input voltage increases, the switch on-time decreases, keeping the output power constant. The offset voltage is proportional to the Latch/Plimit pin voltage and the gain is 0.16; if the Latch/Plimit voltage is 1V, the offset voltage is 0.16V.

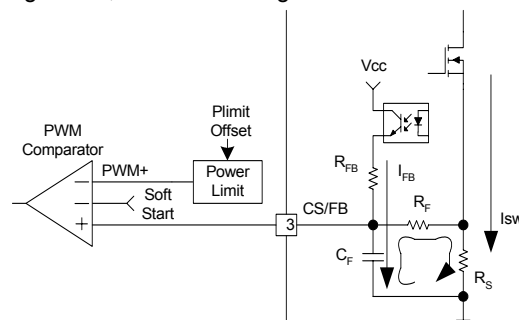

Figure 20. Current-Sense and Feedback Circuits

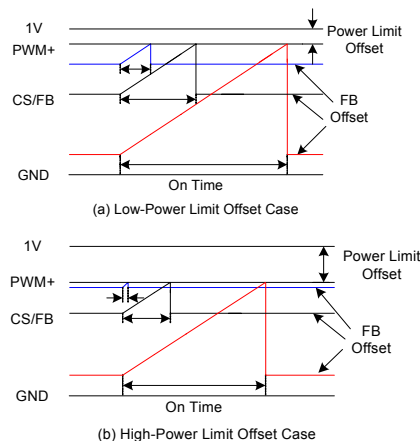

Figure 21. CS/FB Pin Voltage Waveforms

4. Burst-Mode Block

The FAN7602B contains the burst-mode block to reduce the power loss at a light load and no load. A hysteresis comparator senses the offset voltage of the Burst+ for the burst mode, as shown in Figure 22. The Burst+ is the sum of the CS/FB voltage and Plimit offset voltage. The FAN7602B enters burst mode when the offset voltage of the Burst+ is higher than 0.95V and exits the burst mode when the offset voltage is lower than 0.88V. The offset voltage is sensed during the switch off time.

Figure 22. Burst-Mode Block

5. Protection Block

The FAN7602B contains several protection functions to improve system reliability.

5.1 Overload Protection (OLP)

The FAN7602B contains the overload protection function. If the output load is higher than the rated output current, the output voltage drops and the feedback error amplifier is saturated. The offset of the CS/FB voltage representing the feedback information is almost zero. As shown in Figure 23, the CS/FB voltage is compared with 50mV reference when the internal clock signal is high and, if the voltage is lower than 50mV, the OLP timer starts counting. If the OLP condition persists for 22ms, the timer generates the OLP signal. This protection is reset by the UVLO. The OLP block is enabled after the soft-start finishes.

Figure 23. Overload Protection Circuit

5.2 Line Under-Voltage Protection

If the input voltage of the converter is lower than the minimum operating voltage, the converter input current increases too much, causing component failure. Therefore, if the input voltage is low, the converter should be protected. In the FAN7602B, the LUV circuit senses the input voltage using the LUV pin and, if this voltage is lower than 2V, the LUV signal is generated. The comparator has 0.5V hysteresis. If the LUV signal is generated, the output drive block is shut down, the output

voltage feedback loop is saturated, and the OLP initiates if the LUV condition persists more than 22ms.

Figure 24. Line UVP Circuit

5.3 Latch Protection

The latch protection is provided to protect the system against abnormal conditions using the Latch/Plimit pin. The Latch/Plimit pin can be used for the output over-voltage protection and/or other protections. If the Latch/Plimit pin voltage is made higher than 4V by an external circuit, the IC is shut down. The latch protection is reset when the V_{CC} voltage is lower than 5V.

5.4 Over-Voltage Protection (OVP)

If the V_{CC} voltage reaches 19V, the IC shuts down and the OVP protection is reset when the V_{CC} voltage is lower than 5V.

6. Output Drive Block

The FAN7602B contains a single totem-pole output stage to drive a power MOSFET. The drive output is capable of up to 450mA sourcing current and 600mA sinking current with typical rise and fall time of 45ns and 35ns, respectively, with a 1nF load.

Typical Application Circuit

Application	Output Power	Input Voltage	Output Voltage
Adapter	48W	Universal input (85~265V _{AC})	12V

Features

- Low stand-by power (<0.3W at 265V_{AC})
- Constant output power control

Key Design Notes

- All the IC-related components should be placed close to IC, especially C107 and C110.
- If R106 value is too low, there can be subharmonic oscillation.
- R109 should be designed carefully to make V_{CC} voltage higher than 8V when the input voltage is 265V_{AC} at no load.
- R110 should be designed carefully to make V_{CC} voltage lower than OVP when the input voltage is 85V_{AC} at full load.
- R103 should be designed to keep the MOSFET V_{DS} voltage lower than maximum rating when the output is shorted.
